## INTERNATIONAL CHRONOSTRATIGRAPHIC CHART

www.stratigraphy.org

International Commission on Stratigraphy

v 2014/02

Units of all ranks are in the process of being defined by Global Boundary Stratotype Section and Points (GSSP) for their lower boundaries, including those of the Archean and Proterozoic, long defined by Global Standard Stratigraphic Ages (GSSA). Charts and detailed information on ratified GSSPs are available at the website <http://www.stratigraphy.org>. The URL to this chart is found below.

Numerical ages are subject to revision and do not define units in the Phanerozoic and the Ediacaran; only GSSPs do. For boundaries in the Phanerozoic without ratified GSSPs or without constrained numerical ages, an approximate numerical age (-) is provided.

Numerical ages for all systems except Lower Pleistocene, Permian, Triassic, Cretaceous and Precambrian are taken from 'A Geologic Time Scale 2012' by Gradstein et al. (2012); those for the Lower Pleistocene, Permian, Triassic and Cretaceous were provided by the relevant ICS subcommissions.

Coloring follows the Commission for the Geological Map of the World (<http://www.ccgw.org>)

## SVANTE ARRHENIUS (1859-1927)

Arrhenius did very little research in the fields of climatology and geophysics, and considered any work in these fields a hobby. His basic approach was to apply knowledge of basic scientific principles to make sense of existing observations, while hypothesizing a theory on the cause of the “Ice Age.” Later on, his geophysical work would serve as a catalyst for the work of others.

In 1895, Arrhenius presented a paper to the Stockholm Physical Society titled, “On the Influence of Carbonic Acid in the Air upon the Temperature of the Ground.”

This article described an energy budget model that considered the radiative effects of carbon dioxide (carbonic acid) and water vapor on the surface temperature of the Earth, and variations in atmospheric carbon dioxide concentrations. In order to proceed with his experiments, Arrhenius relied heavily on the experiments and observations of other scientists, including Josef Stefan, Arvid Gustaf Högbom, Samuel Langley, Leon Teisserenc de Bort, Knut Angstrom, Alexander Buchan, Luigi De Marchi, Joseph Fourier, C.S.M. Pouillet, and [John Tyndall](#).

Arrhenius argued that variations in trace constituents—namely carbon dioxide—of the atmosphere could greatly influence the heat budget of the Earth. Using the best data available to him (and making many assumptions and estimates that were necessary), he performed a series of calculations on the temperature effects of increasing and decreasing amounts of carbon dioxide in the Earth's atmosphere. His calculations showed that the “temperature of the Arctic regions would rise about 8 degrees or 9 degrees Celsius, if the carbonic acid increased 2.5 to 3 times its present value. In order to get the temperature of the ice age between the 40th and 50th parallels, the carbonic acid in the air should sink to 0.62 to 0.55 of present value (lowering the temperature 4 degrees to 5 degrees Celsius).”

## REMARKABLE WEATHER OF 1911

The Effect of the Combustion  
of Coal on the Climate — What  
Scientists Predict for the Future

By FRANCIS MOLENA

**T**HE year 1911 will long be remembered for the violence of its weather. The spring opened mild and

The mean temperature of every month except November was above the average of that of the 40 years covered by

*Popular Mechanics,*  
March 1912, 393-342

“It is largely the courageous, enterprising, and ingenious American whose brains are changing the world. Yet even the dull foreigner, who burrows in the earth by the faint gleam of his miner's lamp, not only supports his family and helps to feed the consuming furnaces of modern industry, but by his toil in the dirt and darkness adds to the carbon dioxide in the earth's atmosphere so that men in generations to come shall enjoy milder breezes and live under sunnier skies.”

**Earth's energy imbalance** is the difference between the amount of solar energy absorbed by Earth and the amount of energy the planet radiates to space as heat.

**Earth's energy imbalance** is the difference between the amount of solar energy absorbed by Earth and the amount of energy the planet radiates to space as heat.

### Abstract

The dominant external forces influencing the rate of change of the Earth System have been astronomical and geophysical during the planet's 4.5-billion-year existence. In the last six decades, anthropogenic forcings have driven exceptionally rapid rates of change in the Earth System. This new regime can be represented by an 'Anthropocene equation', where other forcings tend to zero, and the rate of change under human influence can be estimated. Reducing the risk of leaving the glacial–interglacial limit cycle of the late Quaternary for an uncertain future will require, in the first instance, the rate of change of the Earth System to become approximately zero.

### Abstract

The dominant external forces influencing the rate of change of the Earth astronomical and geophysical during the planet’s 4.5-billion-year existence, anthropogenic forcings have driven exceptionally rapid rates of change in the Earth System. This new regime can be represented by an ‘Anthropocene equation’ where forcings tend to zero, and the rate of change under human influence can be much greater than the risk of leaving the glacial–interglacial limit cycle of the late Quaternary. This will require, in the first instance, the rate of change of the Earth System to be zero.

Greenhouse gas emissions caused by humans over the past 45 years have increased the rate of temperature rise to 1.7 degrees celsius per century. Photograph: ISS/NASA

# The Diagnosis: Leaving the “Safe Operating Space”

**Table 1.** Rates of change of the Earth System.

	Holocene baseline rate of change	Current rate of change	Magnitude/scale of change	References
<i>Earth System parameter-climate</i>				
Atmospheric CO <sub>2</sub> concentration	~0.17 ppm/century decrease between c. 11k and 7k BP; ~0.30 ppm/century increase between c. 7k BP and 1750	166 ppm/century (average 1970–2015)	~550 times faster than Holocene baseline rate ~100 times faster than the most rapid rise during the last glacial termination. ~10 times faster than the maximum rate of carbon outgassing during the Paleocene-Eocene Thermal Maximum	Ciais et al. (2013) Wolff (2011) Zeebe et al. (2016)
Atmospheric CH <sub>4</sub> concentration	2 ppb/century	575 ppb/century (1984–2015 average)	~285 times faster than Holocene baseline rate. From 1750 to 2012 CH <sub>4</sub> increased by 150% from 722 ppb to 1810 ppb	<a href="http://www.esrl.noaa.gov/gmd/ccgg/trends_ch4/#global_data">http://www.esrl.noaa.gov/gmd/ccgg/trends_ch4/#global_data</a> Saunois et al. (2016) Singarayer et al. (2011)
Global average surface temperature	-0.01°C/century	1.7°C/century (average 1970–2015)	170 times faster than the Holocene baseline rate	Marcott et al. (2013) NOAA (2016)
Sea-level rise	~0 mm/yr from c. 3000 BP to pre-industrial	3.2±0.4 mm/yr (1993–2010)	Average global sea level is currently higher than at any other time within the past ~115,000 years	Church et al. (2013) IPCC (2013)
<i>ES parameter-biosphere</i>				
Extinction rate	0.1 extinctions per million species years	1–10 extinctions per million-species years	10–100 times background rate	Ceballos et al. (2015) De Vos et al. (2015)
Terrestrial biosphere modification	Up to 1700, ~50% of global ice-free land cover was wild; ~5% was intensively used	By 2000, only 25% was wild and 55% was intensively used by humans		Ellis et al. (2010)
Climate-triggered species range shifts	Small compared with range shift during Pleistocene–Holocene transition	Similar or greater than range shifts at beginning and end of the Pleistocene	Future range shifts may be ~10 times greater than during Pleistocene–Holocene transition	Diffenbaugh and Field (2013)
<i>ES parameter-biogeochemical cycles</i>				
Ocean acidity	~0 pH unit/year	-0.0014–0.0024 pH unit/year in surface waters	pH of seawater has decreased by ~0.1 since beginning of industrial era, equivalent to a 26% increase in H <sup>+</sup> ion concentration. Surface-ocean chemistry changes during the Anthropocene are projected to be three to seven times larger and 70 times faster than during a deglaciation. Current OA rate of change is highest in possibly 300 million years	Elsig et al. (2009) Hönisch et al. (2012) Rhein et al. (2013) Zeebe (2012)
N cycle	Biological nitrogen fixation on land: 58 Tg/yr, in the ocean: 140 Tg/yr, and fixation by lightning: 5 Tg/yr	~180 Tg N per year from industrial and intended biological fixation, and 30 Tg N per year from human combustion processes.	Humans now fix as much N as all natural processes combined. This is possibly the largest and most rapid change to the global N cycle in 2.5 billion years.	Fowler et al. (2013) Gruber and Galloway (2008)
P cycle	10–15 Tg P/yr input to soil (pre-industrial weathering)	28–33 Tg P/yr input to soil (from enhanced weather and mining of P for fertilizers)	Up to 3 times more P per year released to environment from human activities compared with Holocene baseline	Carpenter and Bennett (2011)
Sedimentary fluxes		~57,000 Tg/yr of sediments displaced by mineral extraction	Sediment displacement by mineral extraction nearly 3 times greater than global river sediment transport. Human processes have increased sediment flow by erosive processes and reduced sediment flow by dam building	Douglas and Lawson (2000) Steffen et al. (2007, 2015) Syvitski et al. (2009) Zalasiewicz et al. (2014b)

Notes: Current rates of change of key Earth System processes (climate, biosphere and biogeochemical cycles) relative to various time intervals in the geological and historical past. Ranges are included where significant uncertainty exists, for example, extinction rates.

### REVIEW OF THE MONTH

## Capitalism and the Curse of Energy Efficiency

### The Return of the Jevons Paradox

by John Bellamy Foster, Brett Clark and Richard York

(Nov 01, 2010)

The Jevons Paradox is the product of a capitalist economic system that is unable to conserve on a macro scale, geared, as it is, to maximizing the throughput of energy and materials from resource tap to final waste sink. Energy savings in such a system tend to be used as a means for further development of the economic order, generating what Alfred Lotka called the “maximum energy flux,” rather than minimum energy production.

An economic system devoted to profits, accumulation, and economic expansion without end will tend to use any efficiency gains or cost reductions to expand the overall scale of production. Technological innovation will therefore be heavily geared to these same expansive ends. It is no mere coincidence that each of the epoch-making innovations (namely, the steam engine, the railroad, and the automobile) that dominated the eighteenth, nineteenth, and twentieth centuries were characterized by their importance in driving capital accumulation and the positive feedback they generated with respect to economic growth as a whole—so that the scale effects on the economy arising from their development necessarily overshot improvements in technological efficiency.

# Key Points

---

## Baseline

During the Holocene, climate and sea level were exceptionally stable

The Holocene was a “safe operating space for humanity”

## Syndrome

During the last few hundred years, humanity has introduced rapid and large changes

The system is outside the “normal range” and in the dynamic transition into the Post-Holocene; we have increasing disequilibrium

## Diagnosis

Easy access to seemingly unlimited energy allowed humans to accelerate flows in the Earth’s life-support system and sustain rapid population growth and increasing demands

Humans are the “Anthropogenic Cataclysmic Virus” (ACV) in the Earth’s life-support system

- Prepare for loss of coastal cities

## Will a rising tide sink all homes?

Nationwide, almost 1.9 million homes (or roughly 2 percent of all U.S. homes) worth a combined \$882 billion are at risk of being underwater by 2100 if sea levels rise by six feet. Some states will be hit harder than others.

State	Number of Potentially Underwater Properties	Fraction of Total Housing Stock Underwater	Total Value of Potentially Underwater Properties
California	42,353	0.44%	\$49.2B
Texas	46,804	0.61%	\$12B
New York	96,708	2.10%	\$71B
Florida	934,411	12.56%	\$413B
Pennsylvania	2,661	0.06%	\$730M
Georgia	24,379	0.75%	\$10.2B
North Carolina	57,350	1.64%	\$20.6B
New Jersey	10,000	0.10%	\$1.0B

Zillow study:

- 1.8 m by 2100
- 36 U.S. Coastal Cities lost;
- more than 50 cities lose at least 50% of residential real estate
- \$1 Trillion in loss (2% of residential real estate value)

Maine			\$5.1B
New Hampshire	4,064	0.71%	\$1.7B
Rhode Island	4,853	1.47%	\$2.9B
Delaware	11,670	3.09%	\$3.6B

### Fishin' gone?

Because gas solubility decreases as temperatures increase, global warming is likely to cause oxygen loss from the oceans. This could have a detrimental impact on fish populations, the fishing industry, and global food availability. Have such impacts occurred before? Yao *et al.* report sulfur isotopic data from the Paleocene-Eocene Thermal Maximum, an interval around 55 million years ago when atmospheric carbon dioxide concentrations and global temperatures were also high. They found widespread anoxia and resulting high concentrations of hydrogen sulfide, which is toxic to marine organisms. Similar effects could have severe negative effects on ocean ecosystems.

Science, this issue p. **804**

### Abstract

The consequences of global warming for fisheries are not well understood, but the geological record demonstrates that carbon cycle perturbations are frequently associated with ocean deoxygenation. Of particular interest is the Paleocene-Eocene Thermal Maximum (PETM), where the carbon dioxide input into the atmosphere was similar to the IPCC RCP8.5 emission scenario. Here we present sulfur-isotope data that record a positive 1 per mil excursion during the PETM. Modeling suggests that large parts of the ocean must have become sulfidic. The toxicity of hydrogen sulfide will render two of the largest and least explored ecosystems on Earth, the mesopelagic and bathypelagic zones, uninhabitable by multicellular organisms. This will affect many marine species whose ecozones stretch into the deep ocean.

## World wildlife 'fallen 68% in 37 years'

By Rebecca Morelle, Science Correspondent, BBC

© 27 October 2016 | Science & Environment

"We do see particularly strong declines in freshwater species alone, the decline stands at 81% since 1970. This is related to the way water is used and taken out of fresh water systems, and also the fragmentation of freshwater systems through dam building, for example."

Current extinction rates:  
300 times background rate for birds  
80,000 times background rate for mammals

# Prognosis: Journey into the Unknown

## The Ice Age

During the Ice Age, many large mammals roamed the earth, filling out deep branches on the mammal Tree of Life

## The Present

Since then, all the largest species have been chopped off the mammal Tree by extinctions

## The Future?

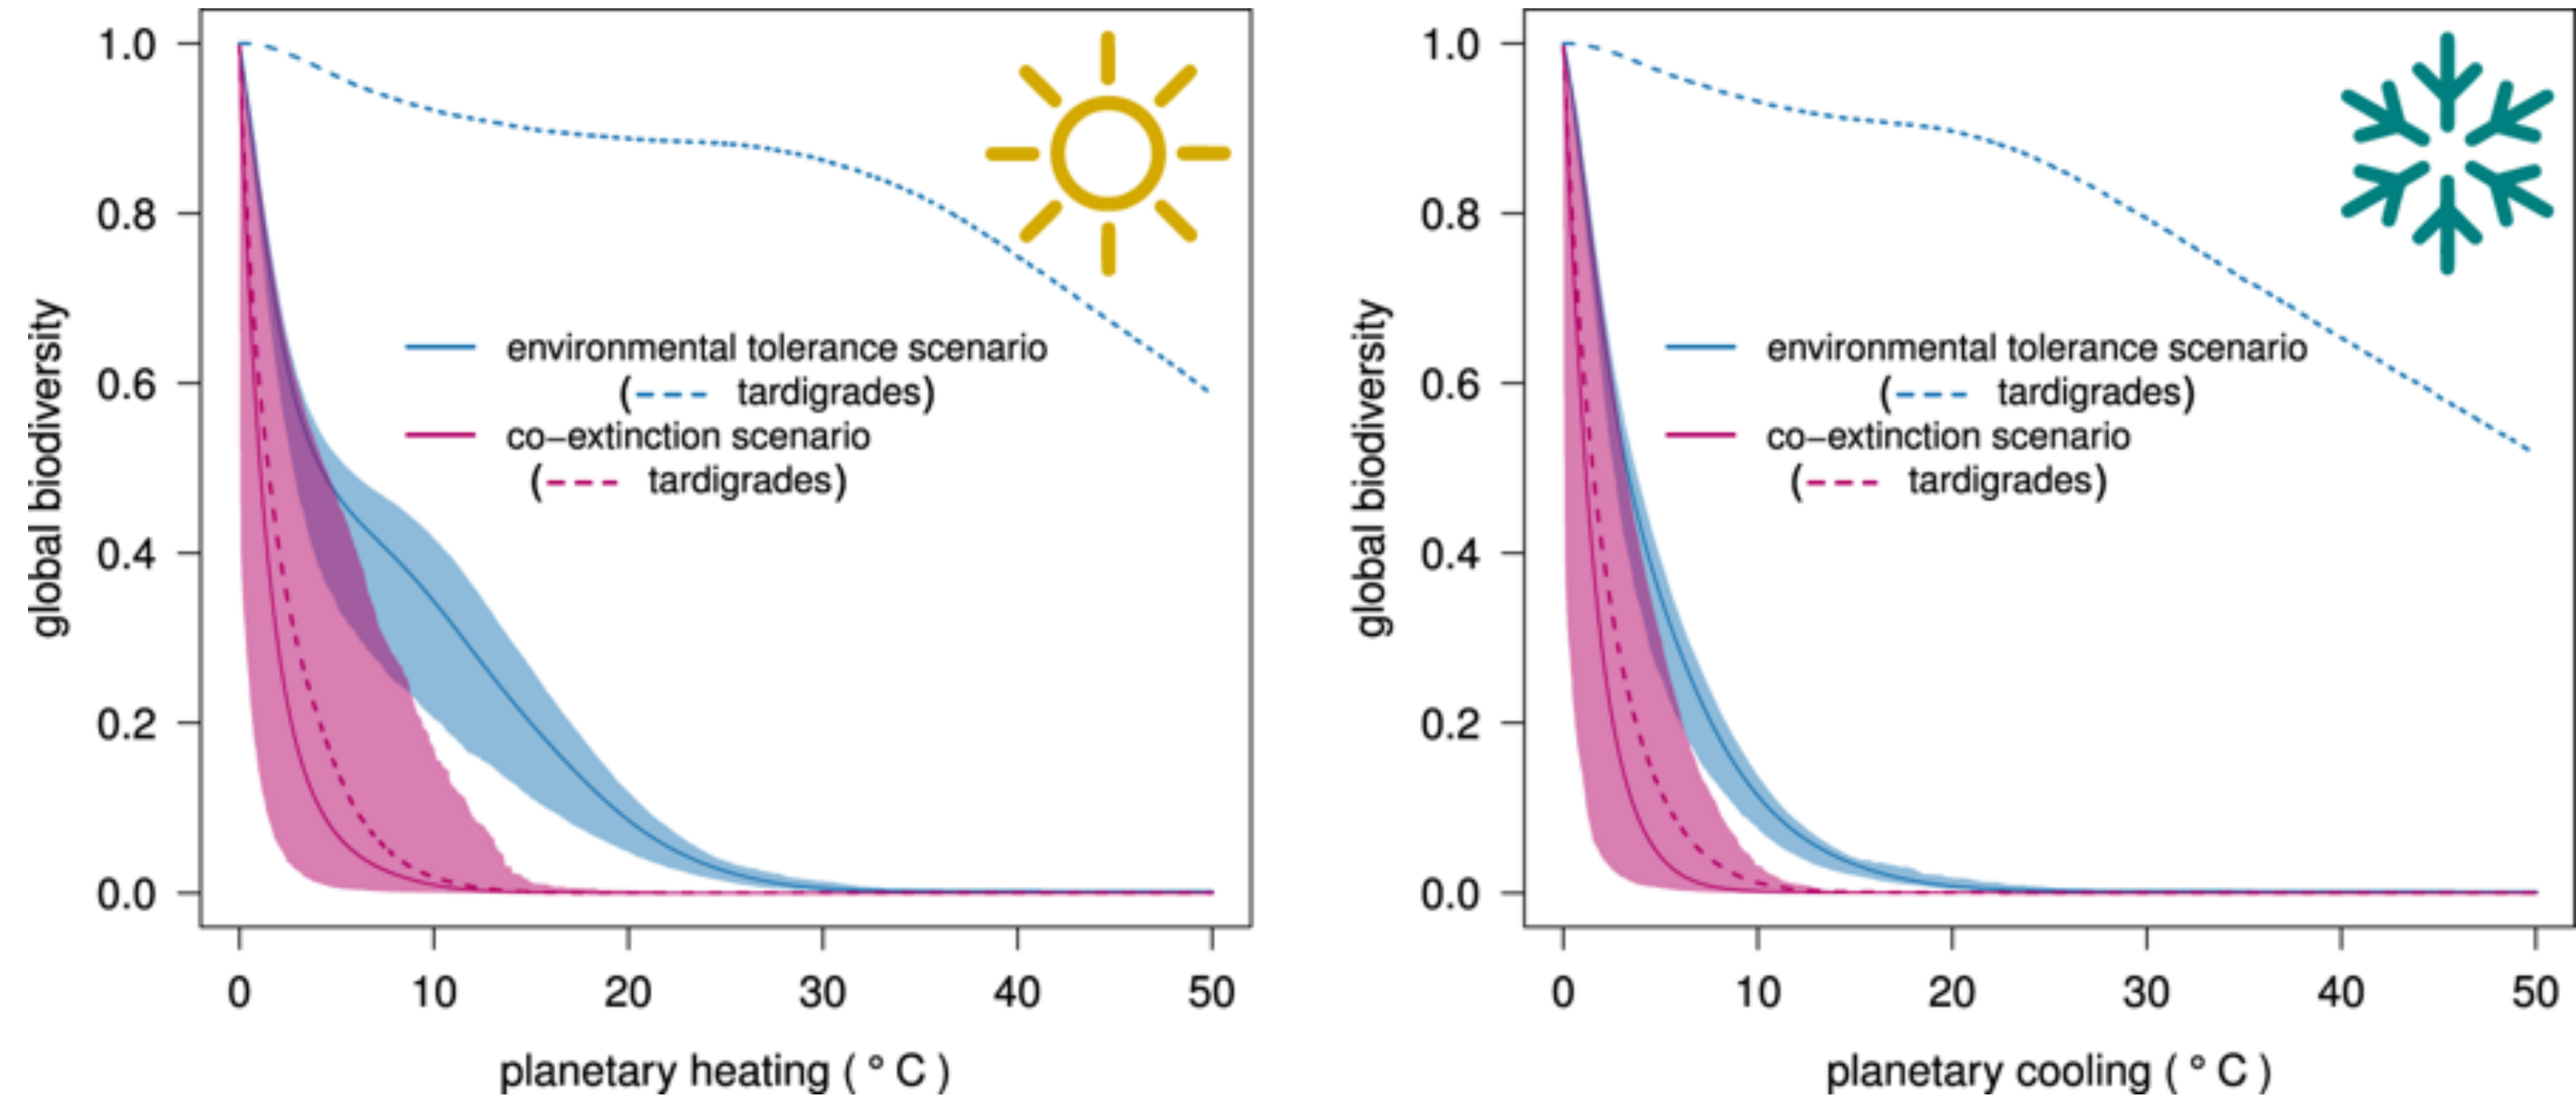

Surviving species will have to diversify for millions of years to restore this missing evolutionary history and regrow the Tree of Life

# Prognosis: Journey into the Unknown

Co-extinctions reduce the robustness of planetary life to catastrophe. Response of global diversity to environmental change: progressive, monotonic increase ('planetary heating'; left panel) or decrease ('planetary cooling'; right panel) trajectories in local temperature. Species either go extinct based only on their tolerance to environmental conditions ('environmental tolerance' scenarios = blue curves), or where species go extinct not only when unable to cope with changed environmental conditions, but also following the depletion of their essential resources ('co-extinction' scenarios = magenta curves). Solid lines represent mean values, and shaded areas indicate the system boundaries (minimum-maximum) arising from 1000 randomly parametrized models (see Methods for details). Dotted lines show the decline in 'tardigrade' (extremophile) species richness in the environmental tolerance (blue) and in the co-extinction scenario (magenta) for both temperature trajectories.

Strona and Bradshaw, 2018

Co-extinctions reduce the robustness of planetary life to catastrophe. Response of global diversity to environmental change: progressive, monotonic increase ('planetary heating'; left panel) or decrease ('planetary cooling'; right panel) Simulated food webs are more robust to global cooling than to heating. We evaluated robustness by 'disassembling' a random sample of 1000 food webs. Disassembly consisted of removing species progressively from the least to the most tolerant to warm ('heating') or cold ('cooling') temperatures. We simulated co-extinctions after each species removal, and then plotted the curves depicting the (co-extinction driven) decline of local diversity following direct species removal. To obtain approximate upper and lower boundaries of robustness, we did two additional disassembly simulations for each food web by removing species in increasing ('best') or decreasing ('worst') order of their expected contribution to network persistence (measured as the number of associated resources per species). For each food web, we also obtained a reference curve by removing species in random order ('random'). Solid lines represent mean values, while shaded areas indicate 99% confidence intervals.

# Key Points

---

## Baseline

During the Holocene, climate and sea level were exceptionally stable

The Holocene was a “safe operating space for humanity”

## Syndrome

During the last few hundred years, humanity has introduced rapid and large changes

The system is outside the “normal range” and in the dynamic transition into the Post-Holocene; we have increasing disequilibrium

## Diagnosis

Easy access to seemingly unlimited energy allowed humans to accelerate flows in the Earth’s life-support system and sustain rapid population growth and increasing demands

Humans are the “Anthropogenic Cataclysmic Virus” (ACV) in the Earth’s life-support system

## Prognosis

We are heading rapidly into a very different system state (tippingpoints; Post-Holocene)

Our knowledge is changing rapidly; there is room for surprises; Foresight is needed

# Modern Climate Change: A Symptom of a Single-Species High-Energy Pulse Syndrome

They are heading for a mono-species system

Homo sapiens keep accumulating “wealth” while destroying their life-support system

Their system knowledge increases, and for the first time, they can see the control levers, knobs and switches that drive the Earth system

But they don't have the control panel, the cockpit to control and operate the system

Plaq, 2000

Before we leave, a recommendation for humanity ...

Importantly, they don't have a design plan and there is no planetary governance to take the system to a future desirable for Homo sapiens

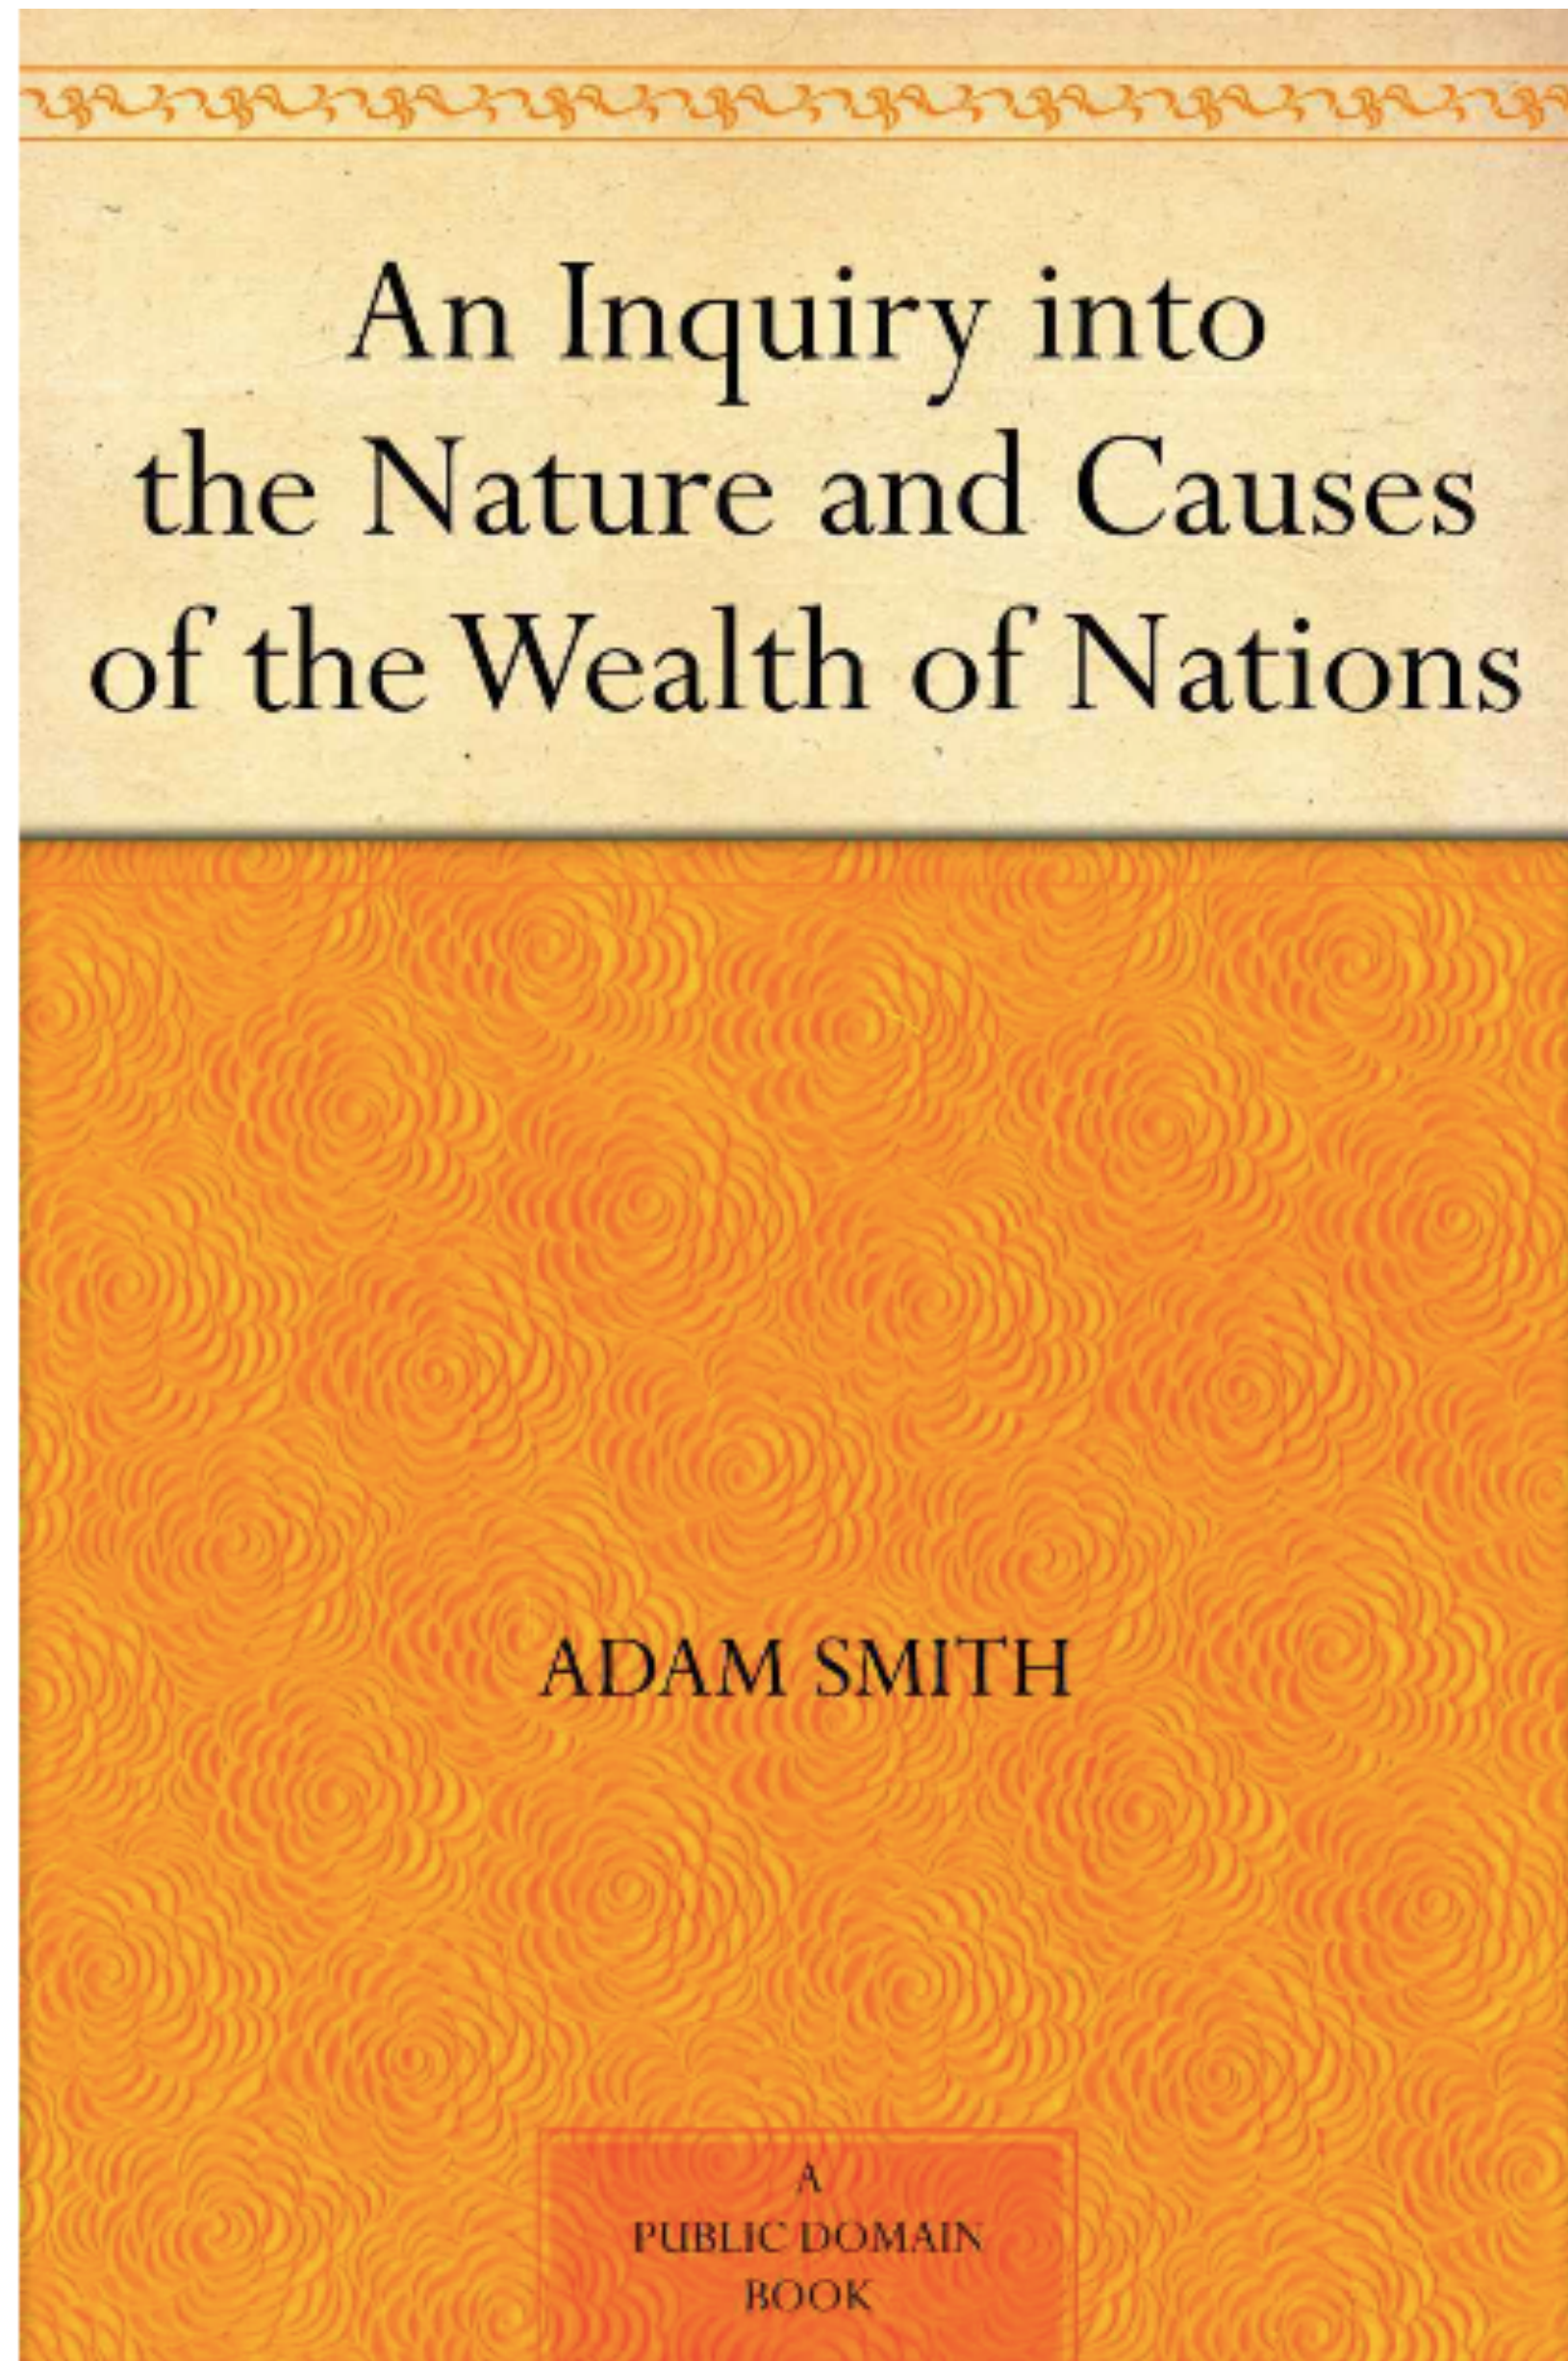

For Homo sapiens, flows are regulated by

- ethics,
- social norms,
- economic rules

- Purpose of economy is to increase human wealth;
- Earth and its natural wealth is basically infinite.

*Smith (1776)*

*Published in 1776*

## Sustainable development goals for people and planet

Planetary stability must be integrated with United Nations targets to fight poverty and secure human well-being, argue **David Griggs** and colleagues.

The United Nations Rio+20 summit in Brazil in 2012 committed governments to create a set of sustainable development goals (SDGs) that would be integrated into the follow-up to the Millennium Development Goals (MDGs) after their 2015 deadline. Discussions on how to formulate these continue this week at UN headquarters in New York. We argue that the protection of Earth's

life-support system and poverty reduction must be the twin priorities for SDGs. It is not enough simply to extend MDGs, as some are suggesting, because humans are transforming the planet in ways that could undermine development gains. As mounting research shows, the stable functioning of Earth systems — including the atmosphere, oceans, forests, waterways, biodiversity and biogeochemical cycles — is

a prerequisite for a thriving global society. With the human population set to rise to 9 billion by 2050, definitions of sustainable development must be revised to include the security of people and the planet. Defining a unified set of SDGs is challenging, especially when there can be conflict between individual goals, such as energy provision and climate-change prevention. But we show here that it is possible. By ▶

Our Message to Humanity: You need an economy that meets the needs of the present while safeguarding Earth's life support systems, on which the welfare of current and future generations depends.

## Safeguarding Our Life Support System

OVERCOMING THE “IMMUTABLE TRUTH” OF GROWTH  
BEING NECESSARY FOR A THRIVING ECONOMY

IN EARLIER COLUMNS, I MADE REFERENCE TO a new definition for sustainable development: a development that meets our needs while safeguarding the Earth's life support system on which we and all future generations depend. Safeguarding our life support system (LSS) seems logical and to be something we all should be eager and able to agree upon.

# Key Points

---

## Baseline

During the Holocene, climate and sea level were exceptionally stable

The Holocene was a “safe operating space for humanity”

## Syndrome

During the last few hundred years, humanity has introduced rapid and large changes

The system is outside the “normal range” and in the dynamic transition into the Post-Holocene; we have increasing disequilibrium

## Diagnosis

Easy access to seemingly unlimited energy allowed humans to accelerate flows in the Earth’s life-support system and sustain rapid population growth and increasing demands

Humans are the “Anthropogenic Cataclysmic Virus” (ACV) in the Earth’s life-support system

## Prognosis

We are heading rapidly into a very different system state (thresholds; Post-Holocene)

Our knowledge is changing rapidly; there is room for surprises; Foresight is needed

## Therapy

Change in the purpose of economy from growing human wealth (growth addiction) to meeting our needs while safe-guarding the life-support system
